

Strings

- A String constant is a sequence of characters in single or double quotation marks 'Hello' or "Hello"
- A String can be assigned to a variable that becomes a string variable `str1 = "Hello World"`
- A String is an array of unchangeable characters represented by Unicode values
- Number of characters in the String `len(str1)`
- The characters in a String can be accessed using square brackets as values in a List

<code>for i in range(0,len(str1)):</code>	<code>for char in str1:</code>	<code>for i in range(-1,-(len(str1)+1),-1):</code>
<code>print(str1[i])</code>	<code>print(char)</code>	<code>print(str1[i])</code>
- A sub-string can be obtained by specifying a range of indexes (slice)

<code>str1[start:end:step]</code>	<code>str1[:3]</code>	<code>str1[2:]</code>	<code>str1[-5:-1]</code>	<code>str1[0:10:2]</code>
	"Hel"	"llo World"	"Worl"	"HloWr"
- Check if a sequence of characters exists in a String

`if "World" in str1 :`
`print("World is in the string")`
- Strings can be combined using format or the concatenation operator +

`str3 = str1 + " " + str(a)`
`a = 20 print("string1: {} integer: {}".format(str1,a)) print(f"string1:{str1} integer:{a}")`

Strings

- Some String built-in methods:

<code>string.count(value)</code>	Returns the number of times that value appears in the string
<code>string.find(value)</code>	Searches the string for value and returns its position
<code>string.format()</code>	Formats values in a string
<code>string.isalnum()</code>	Returns True if all characters are alphanumeric
<code>string.isalpha()</code>	Returns True if all characters are in the alphabet
<code>string.isdigit()</code>	Returns True if all characters are digits
<code>string.islower()</code>	Returns True if all characters are lower case
<code>string.isupper()</code>	Returns True if all characters are upper case
<code>string.lower()</code>	Converts a string into lower case
<code>string.replace(str1,str2)</code>	Returns a string where str1 is replaced by str2
<code>string.split(separator)</code>	Splits the string at the separator (default space), and returns a list
<code>string.strip()</code>	Returns the string with the starting and ending spaces removed
<code>string.upper()</code>	Converts a string into upper case

Some Python built-in functions

<u>abs()</u>	Returns the absolute value of the argument
<u>bool()</u>	Returns the boolean value of the argument
<u>chr()</u>	Returns the character corresponding to the Unicode code argument
<u>complex(real, imag)</u>	Returns a complex number with real and imag values
<u>dict()</u>	Returns a dictionary
<u>dir()</u>	Returns a list of the argument's properties and methods
<u>eval()</u>	Evaluates and executes the argument expression
<u>exec()</u>	Executes the argument code
<u>float()</u>	Returns a floating point number of the argument
<u>format()</u>	Formats a specified value
<u>hex()</u>	Converts the argument number into a hexadecimal value
<u>id()</u>	Returns the id of the argument
<u>input()</u>	Reads user input
<u>int()</u>	Returns an integer number of the argument
<u>isinstance(object, type)</u>	Returns True if an object is of type instance
<u>len()</u>	Returns the length of the argument
<u>list()</u>	Returns a list of the argument
<u>max()</u>	Returns the largest item
<u>min()</u>	Returns the smallest item
<u>ord()</u>	Returns the Unicode integer of the character argument
<u>pow(x,y)</u>	Returns the value of x to the power of y
<u>print()</u>	Prints to the output device
<u>range(start,end,inc)</u>	Returns a sequence of numbers, starting from 0 and increments by 1 (by default)
<u>reversed()</u>	Returns the reversed elements of the argument
<u>round(number,decimals)</u>	Rounds a number to the number of decimals (default 0)
<u>set()</u>	Returns a new set
<u>sorted()</u>	Returns a sorted list
<u>str()</u>	Returns a string of the argument
<u>sum()</u>	Sums the elements
<u>tuple()</u>	Returns a tuple
<u>type()</u>	Returns the type of the argument

Examples of string built-in functions

len(*string*)

Returns the number of characters in the *string*

Ex: **len("Good morning")** R: **12**

chr(*ascii*)

Returns the character corresponding to the *ascii* code (Unicode)

Ex: **chr(65)** R: **A**

ord(*character*)

Returns the ASCII (Unicode) code of the *character*

Ex: **ord("A")** R: **65**
